ON THE \( M_3 \Rightarrow M_1 \) QUESTION

by

GARY GRUENHAGE
ON THE $M_3 \Rightarrow M_1$ QUESTION

Gary Gruenhage

1. Introduction

In 1961, J. Ceder [C] defined the $M_i$-spaces, $i = 1, 2, 3$, proved that $M_1 \Rightarrow M_2 \Rightarrow M_3$, and asked whether any of the implications reversed. H. Junnila [J] and the author [G] independently proved that $M_3$-spaces, usually called "stratifiable spaces," are $M_2$. The question remains whether $M_3 \Rightarrow M_1$, that is, whether every stratifiable space has a $\sigma$-closure-preserving base. Some partial results obtained so far are that the closed image of a metric space is $M_1$ (F. Slaughter [Sl]), and that $\sigma$-discrete stratifiable spaces are $M_1$ [G2]. Recently, R. Heath and Junnila showed that every stratifiable space is the image of an $M_1$-space under a perfect retraction (and hence is a closed subset of an $M_1$-space).

Let us call a space which is a countable union of closed metrizable subspaces an $F_\sigma$-metrizable space. In the first part of this paper, we prove that every stratifiable $F_\sigma$-metrizable space is $M_1$. Many common examples of stratifiable spaces seem to be of this type. For example, all the examples given in Ceder's paper, as well as the chunk-complexes (which he proves to be $M_1$), are $F_\sigma$-metrizable. Hyman's $M$-spaces [H], called paracomplexes and proved $M_1$ by J. Nagata [N], are also of this type.

Another interesting class of stratifiable spaces is the following. Let $I$ be an index set, and for each $i \in I$,
let \( X_i \) be a stratifiable space. Let \( p \in \prod_{i \in I} X_i \), where "\( \prod \)" denotes the box product. Let \( Y = \{ x \in \prod_{i \in I} X_i : x(i) = p(i) \} \) for all but finitely many \( i \in I \). Borges [B_3] proved that if each \( X_i \) is stratifiable, so is \( Y \). It is not hard to show that if each \( X_i \) is \( F_\sigma \)-metrizable, then so is \( Y \); hence \( Y \) is \( M_1 \) in this case.

In [G_3], we asked whether a stratifiable space which has a \( \sigma \)-discrete network consisting of compact sets is \( M_1 \). Since compact stratifiable spaces are metrizable, our result implies an affirmative answer to this question.

Unfortunately, the class of stratifiable \( F_\sigma \)-metrizable spaces is not closed under closed maps. In fact, the closed image of a metric space need not be \( F_\sigma \)-metrizable [F]. It must be \( M_1 \), though, by Slaughter's result mentioned above. Now suppose a space \( X \) has the following property: whenever \( H \) and \( K \) are closed subsets of \( X \) with \( H \subseteq K \), then \( H \) has a \( \sigma \)-closure-preserving outer base in \( K \) (i.e., there is a \( \sigma \)-closure-preserving collection \( \mathcal{U} \) of relatively open subsets of \( K \) such that whenever \( H \subseteq O, O \) open, there exists \( U \in \mathcal{U} \) with \( H \subseteq U \subseteq O \)). In the second section of this paper, we prove that if an \( M_1 \)-space \( X \) has the above property, then every closed image of \( X \) is \( M_1 \) and has the same property. From the fact that stratifiable \( F_\sigma \)-metrizable spaces are \( M_1 \), it is easily shown that they also have the above property. Thus every closed image of a stratifiable \( F_\sigma \)-metrizable space is \( M_1 \). This generalizes Slaughter's theorem, and answers a question of Nagata concerning the paracomplexes mentioned above.
Nagata also showed that if $X$ is a paracomplex, then $\text{Ind } X \leq n$ if and only if $X$ has a $\sigma$-closure-preserving base $\beta$ such that $\text{Ind}(\beta B) \leq n - 1$ for every $B \in \beta$. He asked if this result is true for any $M_1$-space. Mizokami [M] showed that it is true for an $M_1$-space which is $F_\sigma$-metrizable and satisfies a certain further condition. With our techniques, we can show it is true for any stratifiable $F_\sigma$-metrizable space.

2. Definitions and Other Preliminaries

All spaces are assumed to be regular. Let $A^0$ denote the interior of a set $A$. A collection $\zeta$ of subsets of a space $X$ is interior-preserving if whenever $\zeta' \subseteq \zeta$, then $(\cap \zeta')^0 = \cap \{G^0 : G \in \zeta'\}$. A collection $\mathcal{H}$ of subsets of $X$ is closure-preserving if whenever $\mathcal{H}' \subseteq \mathcal{H}$, then $\bigcup \mathcal{H}' = \bigcup \{H : H \in \mathcal{H}'\}$. It is easy to see that the set of complements of an interior-preserving family is closure-preserving, and vice-versa.

If $H$ is a subset of a space $X$, an outer base for $H$ is a collection $\mathcal{U}$ of open subsets of $X$ such that whenever $H$ is contained in an open set $O$, then there exists $U \in \mathcal{U}$ such that $H \subseteq U \subseteq O$.

A collection $\beta$ is a quasi-base for $X$ if whenever $x \in U$, $U$ open, there exists $B \in \beta$ such that $x \in B^0 \subseteq B \subseteq U$. ($B^0$ denotes the interior of $B$.) A space $X$ is an $M_1$-space ($M_2$-space) if $X$ has a $\sigma$-closure-preserving base (quasi-base). An $M_3$-space, or stratifiable space, is the same as an $M_2$-space.
We will often use the following characterization of $M_2$-spaces due to Nagata [\(N_2\)].

**Theorem 2.1 (Nagata).** A regular space $X$ is an $M_2$-space if and only if for each $x \in X$ and $n \in \omega$, there exists an open neighborhood $g_n(x)$ of $x$ such that

1. $y \in g_n(x) \Rightarrow g_n(y) \subseteq g_n(x)$; and
2. if $H$ is closed and $x \notin H$, there exists $n \in \omega$ such that $x \notin \bigcup_{x \in H} g_n(x)$.

Clearly, we may assume $g_0(x) \supseteq g_1(x) \cdots$.

A collection $J$ is a network for $X$ if whenever $x \in U$, $U$ open, there exists $F \in J$ such that $x \in F \subseteq U$. $X$ is a $\sigma$-space if $X$ has a $\sigma$-discrete network.

A space $X$ is monotonically normal if for every pair $(H,K)$ of disjoint closed subsets, there exists an open set $D(H,K)$ such that

1. $H \subseteq D(H,K) \subseteq \overline{D(H,K)} \subseteq X - K$;
2. $H \subseteq H'$ and $K \supseteq K' \Rightarrow D(H,K) \subseteq D(H',K')$.

We shall be using the fact that stratifiable spaces are paracompact and perfectly normal [C], that they are $\sigma$-spaces [H], and that they are monotonically normal [HLZ]. Also, every subspace of a stratifiable space is stratifiable [C], and every closed image of a stratifiable space is stratifiable [B].

3. **Main Results, Outlines of the Proofs, and Some Questions**

Since the proof of our main results are rather long and tedious, we will defer them to later sections, giving only brief outlines here.
Theorem 3.1. Let $X$ be stratifiable and $F_\sigma$-metrizable. Then $X$ is $M_1$. Also, $\text{Ind } X \leq n$ if and only if $X$ has a $\sigma$-closure-preserving base $B$ such that $\text{Ind}(\omega B) \leq n-1$ for each $B \in B$.

Outline of proof. Suppose $X$ is stratifiable. Then there exist $g_n(x)$'s satisfying the conditions of Theorem 2.1. The standard way to get a $\sigma$-closure-preserving quasi-base back from the $g_n(x)$'s is as follows. For each closed set $H$, define $G_n(H) = \bigcup_{x \in H} g_n(x)$. It is easy to see from property (1) of Theorem 2.1 that

$$\mathcal{G}_n = \{G_n(H) : H \text{ is closed}, H \subset X\}$$

is interior-preserving. Hence,

$$\beta_n = \{X - G_n(H) : H \text{ closed}, H \subset X\}$$

is closure-preserving, and from property (2), $\bigcup_{n \in \omega} \beta_n$ is a closed quasi-base. A naive attempt to get a $\sigma$-closure-preserving base would be to define

$$\beta'_n = \{(X - G_n(H))^o : H \text{ closed}, H \subset X\}.$$ 

However, $\beta'_n$ may fail to be closure-preserving. But it turns out that if the $G_n(H)$'s are regular open sets, then $\beta'_n$ will be closure-preserving. (See Lemma 5.1.)

So we construct $g_n(x)$'s satisfying the conditions of Theorem 2.1 so that the corresponding $G_n(H)$'s are regular open. We do this by constructing a certain sequence $V_0, V_1, \ldots$ of locally finite open covers of $X$, and then use the $V_i$'s to construct the $g_n(x)$'s, so that:

(i) each $g_n(x)$ is an element of some $V_i$;

(ii) for each $m \in \omega$, every union of elements of $\bigcup_{i \leq m} V_i$ is regular open; and
(iii) if \( H \) is closed and \( y \notin \bigcup_{x \in H} g_n(x) \), then there exists an integer \( k \) such that
\[
y \notin \text{Cl}(\bigcup_{x \in H} g_n(x) : x \in H, g_n(x) \notin \bigcup_{i \leq k} V_i).
\]
It easily follows that \( G_n(H) = \bigcup_{x \in H} g_n(x) \) is regular open whenever \( H \) is closed. The \( T_0 \)-metrizable hypothesis is used to obtain property (iii). It is possible to construct \( V_0, V_1, \ldots \) and the \( g_n(x) \)'s satisfying (i) and (ii) in any stratifiable space.

The "if" part of the last statement of Theorem 3.1 is a result of Nagata [N2]. To obtain the "only if" part, we show that if \( \text{Ind} X \leq n \), we can construct the \( V_i \)'s so that \( \text{Ind}(\exists V) \leq n-1 \) for each \( V \in V_i \). It then follows that \( \text{Ind}(\exists B) \leq n-1 \) for each \( B \in B_n' \).

**Theorem 3.2.** Suppose \( X \) is stratifiable and has the following property: whenever \( H \) and \( K \) are closed subsets of \( X \) with \( H \subset K \), then \( H \) has a \( \sigma \)-closure-preserving outer base in \( K \). Then every closed image of \( X \) has the same property, and is therefore \( M_1 \).

**Outline of proof.** Let (*) denote the property of Theorem 3.2. Any stratifiable space satisfying (*) is \( M_1 \). This follows easily from the facts that every closed subset has a \( \sigma \)-closure-preserving outer base, and that stratifiable spaces are \( \sigma \)-spaces.

Let \( f \) be a closed map of \( X \) onto \( Y \), where \( X \) is stratifiable and satisfies (*). Since every closed subset \( K \) of \( Y \) is the closed image of a stratifiable space satisfying (*), namely \( f^{-1}(K) \), it is enough to show that every closed
image of a stratifiable space satisfying (*) has the property that every closed subset has a $\sigma$-closure-preserving outer base. So we are done if we show that $Y$ has this property.

By a theorem of Okuyama [0], $Y = Y' \cup Y''$, where $f^{-1}(y)$ is compact for each $y \in Y'$, and $Y''$ is $\sigma$-discrete. We use this to show that $Y = Y_0 \cup Y_1$, where $Y_0$ is a closed irreducible image of a closed subset $X_0$ of $X$, and $Y_1$ is open and $\sigma$-discrete. From results in [BL], it follows that every closed subset of $Y_0$ has a $\sigma$-closure-preserving outer base in $Y_0$. Thus $Y$ can be written as the union of a closed subspace having the property we want, and an open $\sigma$-discrete subspace. The final step is to show that any stratifiable space which admits such a decomposition also has the property that every closed subset has a $\sigma$-closure-preserving outer base.

Remark. For stratifiable spaces, property (*) is equivalent to the following property: whenever $H$ and $K$ are closed subsets of $X$ with $H \subseteq K$, then $K/H$ is $M_1$.

Corollary 3.3. The closed image of a stratifiable $F_\sigma$-metrizable space is $M_1$.

Proof. Suppose $X$ is stratifiable and $F_\sigma$-metrizable. Let $H \subseteq K \subseteq X$, where $H$ and $K$ are closed. Then $K/H$ is stratifiable and $F_\sigma$-metrizable, hence $M_1$. By the above remark, $X$ satisfies the conditions of Theorem 3.2.

It is not known whether every $M_1$-space satisfies the property of Theorem 3.2. In fact, it is not known if
every closed subset of an $M_1$-space is $M_1$. However, the result of Heath and Junnila mentioned in the introduction implies, as they note, that this question is equivalent to the $M_3 \Rightarrow M_1$ question. It is also not known whether every closed subset of an $M_1$-space has a $\sigma$-closure-preserving outer base. But if not, then by results of Ceder, there is a stratifiable space which is not $M_1$. On the other hand, Borges and Lutzer [BL] have shown that if each point of a stratifiable space has a $\sigma$-closure-preserving base, then every stratifiable space is $M_1$.

Borges and Lutzer have also shown that if every closed subspace of a space $X$ is $M_1$, then every perfect image of $X$ is $M_1$. This suggests the following question, which would generalize Theorem 3.2 if answered affirmatively.

*Question 3.4.* If every closed subspace of a space $X$ is $M_1$, is every closed image of $X$ also $M_1$?

A class of spaces which Heath and Junnila called $M_0$-spaces may have an important role to play in settling the $M_3 \Rightarrow M_1$ question. An $M_0$-space is a space which has a $\sigma$-closure-preserving base of open and closed sets. It is easy to see that every subspace of an $M_0$-space is $M_0$. Thus every perfect image of an $M_0$-space is $M_1$. Recently, Junnila [J2] has obtained an alternate proof that stratifiable $F_\sigma$-metrizable spaces are $M_1$ by showing that they are perfect images of $M_0$-spaces. Heath and Junnila ask whether every stratifiable space is the perfect image of an $M_0$-space. If so, then $M_3 \Rightarrow M_1$. Our next corollary
shows that it would be enough (for the purpose of obtaining $M_3 \Rightarrow M_1$) to prove that every stratifiable space is the closed image of an $M_0$-space.

**Corollary 3.5.** The closed image of an $M_0$-space is $M_1$.

**Proof.** We show that every $M_0$-space $X$ satisfies the property of Theorem 3.2. If $K \subseteq X$, then $K$ is $M_0$. By mimicking Ceder's proof that every closed subset of an $M_2$-space has a closure-preserving outer quasi-base, we see that every closed subset of $K$ has a closure-preserving base in $K$.

The class of stratifiable $F_\sigma$-metrizable spaces is not closed under closed maps or countable products. These are still $M_1$, of course. In fact, since products of perfect maps are perfect, the countable product $X$ of stratifiable $F_\sigma$-metrizable spaces is the perfect image of an $M_0$-space. Hence $X$ satisfies the property of Theorem 3.2, and so every closed subspace and closed image of $X$ is $M_1$. But further iterations of the procedures of taking closed subspaces, closed images, and countable products, produces spaces that I can't prove are $M_1$. What one might aim for is a solution to the following:

**Problem 3.6.** Find a class of $M_1$-spaces which contains the $F_\sigma$-metrizable spaces, and which is closed under closed subspaces, closed images, and countable products.

Note that the class of stratifiable $F_\sigma$-metrizable spaces is closed under arbitrary subspaces, perfect images,
and finite products. The class of stratifiable spaces satisfying the property of Theorem 3.2 is closed under closed subspaces and closed images. Thus one would have a solution to the Problem 3.6 if one could show that this property is closed under countable products. For another approach, note that the class of perfect images of $M_0$-spaces satisfies all the desired properties except perhaps closure under closed images.

Although we don't do it here, the techniques of section 6 can be used to show that if a stratifiable space $X$ is the union of a closed $M_1$-space and an $F_0$-metrizable space, then $X$ is $M_1$. This suggests a couple of questions, for which affirmative answers to both (or a negative answer to one) would obviously settle the $M_3 \Rightarrow M_1$ question.

**Question 3.7.** If a stratifiable space $X$ is a countable union of a closed $M_1$ subspaces, is $X M_1$?

**Question 3.8.** Is every stratifiable space the countable union of closed $M_1$ subspaces?

### 4. Preliminary Lemmas

In this section we present a series of lemmas on regular open sets, leading up to the result that in a paracompact hereditarily normal space, every open cover has a locally finite refinement $\mathcal{V}$ such that every union of elements of $\mathcal{V}$ is regular open. In fact, if $\mathcal{W}$ is any locally finite collection such that every union of elements of $\mathcal{W}$ is regular open, then $\mathcal{V}$ can be constructed so that
every union of elements of $V \cup W$ is regular open.

**Lemma 4.1.** Let $X$ be a hereditarily normal space. Suppose $U$, $V$, and $U \cup V$ are regular open, and $H$ is a relatively closed subset of $V$. Suppose $\overline{H}$ is contained in an open set $O$. Then there is a set $W$ such that $H \subseteq W \subseteq V$, $\overline{W} \subseteq O$, and both $W$ and $U \cup W$ are regular open. If $X$ is perfectly normal, $\text{Ind } X \leq n$, and $\text{Ind}(\partial U) \leq n-1$, then we can obtain $\text{Ind}(\partial W) \leq n-1$.

**Proof.** Let $O'$ be an open set such that $H \subseteq O' \subseteq \overline{O'} \subseteq O$. Using the hereditary normality $X$, we can find open sets $V_1$ and $V_2$ such that

$$H \subseteq V_1 \subseteq \overline{V}_1 \subseteq V_2 \subseteq \overline{V}_2 \subseteq V \cap O'$$

where $\overline{A}^V$ denotes the closure of $A$ in the subspace $V$. Now let $W = \overline{V}_1 \cup U \cap \overline{V}_2$. We claim that $W$ has the desired properties.

Clearly, $H \subseteq W \subseteq V$, and $\overline{W} \subseteq O$. Also, since the intersection of two regular open sets is regular open, $W$ is regular open. It remains to show $W \cup U$ is regular open. To see this, suppose $p \in \overline{W \cup U} - W \cup U$. Observe that $\overline{W \cup U} = \overline{V}_1 \cup U$. Thus $p \in \overline{V}_1 \cup U - U$. Hence $p \in \overline{V}_1$, since $U$ is regular open. Also, $p \in \overline{V \cup U} - U = (V \cup U) - U$, so $p \in V$. Hence $p \in \overline{V}_1 \cap V \subseteq V_2$. So we have $p \in \overline{V}_1 \cup U \cap \overline{V}_2 = W$, contradiction.

To see the last statement, note that $\partial W \subseteq \partial V_1 \cup \partial V_2 \cup \partial U$. Since $\text{Ind } V \leq n$, we can obtain $\text{Ind}(\partial V_i) \leq n-1$, $i = 1,2$, where "$\partial V$" denotes the boundary of a set in the subspace $V$. Now $\partial V_i = [\partial V_i \cap \partial V] \cup \partial V_i$. Thus $\text{Ind}(\partial V_i) \leq n-1$, and so $\text{Ind}(\partial V_1 \cup \partial V_2 \cup \partial U) \leq n-1$. Thus $\text{Ind}(\partial W) \leq n-1$. 

Lemma 4.2. If $\mathcal{U}$ is a collection of subsets of a space $X$ such that every finite union of elements of $\mathcal{U}$ is regular open, then every finite union of finite intersections of elements of $\mathcal{U}$ is regular open.

Proof. This follows from the fact that a finite union of finite intersections of elements of $\mathcal{U}$ can be written as the finite intersection of finite unions of elements of $\mathcal{U}$, and that a finite intersection of regular open sets is regular open.

Lemma 4.3. Suppose $\mathcal{U}$ is a finite collection of open sets of a hereditarily normal space $X$ such that every union of elements of $\mathcal{U}$ is regular open. Let $H \subseteq O$, $H$ closed, $O$ open. Then there exists a set $W$ such that $H \subseteq W \subseteq O$, and every union of elements of $\mathcal{U} \cup \{W\}$ is regular open.

If $X$ is perfectly normal, $\text{Ind}(X) \leq n$, and $\text{Ind}(\Theta \mathcal{U}) \leq n-1$ for each $U \in \mathcal{U}$, then we can obtain $\text{Ind}(\Theta W) \leq n-1$.

Proof. If $|\mathcal{U}| = 1$, apply Lemma 1 with $U$ the element of $\mathcal{U}$, $V = X$, and $H$ and $O$ as in the hypothesis of this lemma. The set $W$ guaranteed by Lemma 4.1 is easily seen to satisfy the desired conditions.

Now suppose $|\mathcal{U}| = n > 1$. Let $\mathcal{U} = \{U_0, U_1, \ldots, U_{n-1}\}$. Let $W_o$ be a regular open set such that $H \subseteq W_o \subseteq \overline{W_o} \subseteq O$, and $(\cup \mathcal{U}) \cup W_o$ is regular open.

Suppose $W_k$ has been defined, $k < n$. For each subset $I$ of $k + 1$ distinct elements of $n = \{0, 1, \ldots, n-1\}$, let $H(I) = (\Theta W_k) \cap (\bigcap_{i \in I} U_i)$. Then the hypotheses of Lemma 4.1 are satisfied with $U = \cup_{j \not\in I} U_j$, $V = \bigcap_{i \in I} U_i$, $H = H(I)$, and $O$ as in this lemma. (Note the use of Lemma 4.2 to get $U \cup V$...
regular open.) Let $W(I)$ be the set given by Lemma 4.1, and let

$$W_{k+1} = W_k \cup \left( \bigcup \{ W(I) : I \subseteq n, |I| = k + 1 \} \right).$$

Let $W = W_n$. We claim that $W$ has the desired property. To see this, assume $M \subseteq U \cup \{ W \}$, and $x \in \overline{U} - U$. Clearly, we may assume $W \in M$ and $x \in \overline{W}$.

Let $I = \{ i < n : x \in U_i \}$, and let $m = |I|$. If $m = 0$, then $x \in (U \cup \omega) \cap W = (U \cup \omega) \cap W = (U \cup \omega) \cap W$, contradiction. So we may assume $m > 1$. Then $x \notin \overline{W}_{m-1}$, for otherwise $x \in \overline{\bigcup_{m-1} W} \cap (\bigcap_{i \in I} U_i) = H(I) \subseteq W(I) \subseteq W$. So $i \in I$

there is an open set $G$ such that

$$x \in G \subseteq (U \cup \omega) \cap (\bigcap_{i \in I} U_i) \cap (X - \overline{W}_{m-1}).$$

Since $W(I) \cup (U \cup U_j)$ is regular open and doesn't contain $x$, there exists $y \in G$ with $y \notin \overline{W(I) \cup (U \cup U_j)}$. But $y \notin \overline{U} - W$, so $y \notin \overline{U(M - \{ W \})}$ or $y \in \overline{W}$. Since $\overline{U(M - \{ W \})} \subseteq \overline{U}_j$, it must be true that $y \in \overline{W}$. Thus there exists a nonempty set $J \subseteq n$ such that $y \in \overline{W(J)}$. Since $y \notin \overline{W}_{m-1}$, we have $|J| \geq m$. Since $y \notin \overline{W(I)}$, we have $J \neq I$. Therefore, there exists $j_0 \in J - I$. But $\overline{W(J)} = \bigcap_{i \in J} U_i \subseteq \bigcup_{j \in J} U_j$, contradicting $y \notin \overline{U} - U_j$.

Thus $W$ has the desired property. The last statement of Lemma 4.3 follows because $W$ is the union of a finite number of sets obtained from the application of Lemma 4.1.

**Lemma 4.4.** Let $U$ be an open cover of a paracompact hereditarily normal space $X$, and let $V$ be a locally finite collection such that every union of elements of $V$
is regular open. Then there is a locally finite refinement $\mathcal{W}$ of $\mathcal{U}$ such that every union of elements of $\mathcal{V} \cup \mathcal{W}$ is regular open. If $X$ is perfectly normal, $\text{Ind} X \leq n$, and $\text{Ind}(3\mathcal{V}) \leq n-1$ for each $\mathcal{V} \in \mathcal{V}$, then we can obtain $\text{Ind}(3\mathcal{W}) \leq n-1$ for each $\mathcal{W} \in \mathcal{W}$.

**Proof.** Let $\mathcal{J} = \cup_{n \in \omega} \mathcal{J}_n$ be a locally finite open cover of $X$ by sets whose closures refine $\mathcal{U}$ and meet only finitely many elements of $\mathcal{V}$, and such that each $\mathcal{J}_n$ is discrete. Let $\mathcal{G} = \{G_F : F \in \mathcal{J}\}$ be a shrinking of $\mathcal{J}$; i.e., $\mathcal{G}$ is an open cover such that $\overline{G}_F \subseteq F$ for each $F \in \mathcal{J}$. Let $\mathcal{V}(F) = \{V \in \mathcal{V} : V \cap F \neq \emptyset\}$. For each $F \in \mathcal{J}_0$, let $W_F$ be the set given by Lemma 4.3 where $\mathcal{U} = \mathcal{V}(F)$, $H = \overline{G}_F$, and $O = F$.

Then $\overline{G}_F \subseteq W_F \subseteq F$, and every union of elements of $\mathcal{V} \cup \{W_F : F \in \mathcal{J}_0\}$ is regular open. Let $\mathcal{W}_0 = \{W_F : F \in \mathcal{J}_0\}$.

Now suppose that for each $F \in \mathcal{J}_k$, $k < n$, we have defined a $W_F$ such that

(i) $\mathcal{W}_k = \{W_F : F \in \mathcal{J}_k\}$ is a discrete collection of open sets;

(ii) if $F \in \mathcal{J}_k'$, then $\overline{G}_F \cup \cup_{j < k} W_j \subseteq W_F \subseteq F$;

(iii) if $F \in \mathcal{J}_k'$, then $W_F \cap G_{F'} = \emptyset$ whenever $F' \in \mathcal{J}_j$ with $j < k$;

(iv) every union of elements of $\mathcal{V} \cup \cup_{j < k} W_j$ is regular open.

To define $W_F$ for $F \in \mathcal{J}_n$, let $O = \{O_F : F \in \mathcal{J}_n\}$ be a discrete collections of open sets such that

$\overline{G}_F \cup \cup_{k < n} W_k \subseteq O_F \subseteq F$, and

$O_F \cap (\cup \{G_F : F \in \mathcal{J}_k', k < n\}) = \emptyset$.\[90\]
This is possible, since \( \bigcup \{ G_F : F \in \mathcal{F}_k, k < n \} \subseteq \bigcup_{k<n} (\bigcup \{ \mathcal{U}_k \}) \).

Now, for each \( F \in \mathcal{F}_n \), let \( W_F \) be the set given by Lemma 4.3 applied to the case where \( \mathcal{U} = \mathcal{V}(F) \cup \{ \mathcal{U}_k : k < n \}, H = \overline{G_F} - \bigcup_{k<n} (\bigcup \{ \mathcal{U}_k \}) \), and \( O = O_F \).

It is easy to check that \( W_n = \{ W_F : F \in \mathcal{F}_n \} \) satisfies properties (i)-(iii) above. To see that (iv) is satisfied, suppose \( x \in \overline{\bigcup_{k=n} W} - \bigcup_{k<n} W \), where \( \bigcup_{k<n} \mathcal{U} \bigcup (\bigcup \{ \mathcal{U}_k \}) \). Since this collection is locally finite, we may assume \( M \) is finite and \( x \in \overline{M} - M \) for every \( M \in \mathcal{M} \). Let \( I = \{ k < n : M \cap \mathcal{U}_k \neq \emptyset \} \).

For each \( i \in I \), \( x \notin \mathcal{U}_i \) since \( \mathcal{U}_i \) is discrete and \( x \in \overline{W} - W \) for some \( W \in \mathcal{W}_i \). By the induction hypothesis, we can assume there exists \( W_F \in M \cap \mathcal{W}_n \), where \( F \in \mathcal{F}_n \). Then \( M \cap \mathcal{V} = M \cap \mathcal{V}(F) \), since \( x \in \overline{W} \subseteq F \). Thus \( x \) is in the interior of the closure of \( \bigcup \{(M \cap \mathcal{V}(F)) \cup \{ \mathcal{U}_i : i \in I \} \cup \{ W_F \} \} \), but is not in this set, contradicting the way \( W_F \) was defined (i.e., the above set must be regular open). Thus \( W_n \) satisfies (iv).

Let \( W = \bigcup_{n \in \omega} W_n \). That \( W \) is a refinement of \( \mathcal{U} \) follows from property (ii). That \( W \) is locally finite follows from (i) and (iii). And that every union of elements of \( \mathcal{V} \cup \mathcal{U} \) is regular open follows from (iv) and the local finiteness.

Let us see how to obtain the last statement of Lemma 4.4. First note that under the hypotheses we can get \( \text{Ind}(\partial W) \leq n-1 \) for \( W \in \mathcal{W}_o \), since these sets were also obtained from Lemma 4.3. If it's true for \( W \in \bigcup \{ W_k : k < n \} \), then it's also true for \( W \in \mathcal{W}_n \), since these sets were also
obtained from Lemma 4.3, with the $\mathcal{U}$ of Lemma 4.3 being a subset of $\mathcal{V}$ together with $\{\cup^{k}_{k}: k < n\}$, and $\Ind(\mathcal{A}(\cup^{k}_{k})) \leq n-1$ for $k < n$ since each $\cup^{k}_{k}$ is discrete.

5. Stratifiable $F_\sigma$-Metrizable Spaces

In this section, we prove that stratifiable $F_\sigma$-metrizable spaces are $M_1$. First, an easy lemma.

Lemma 5.1. Let $\mathcal{U}$ be an interior-preserving collection of regular open subsets of a space $X$. Then $\{(X - U)^O: U \in \mathcal{U}\}$ is closure-preserving.

Proof. Suppose $\mathcal{U}' \subset \mathcal{U}$, and $x \in \bigcup\{(X - U)^O: U \in \mathcal{U}'\}$. Suppose for each $U \in \mathcal{U}'$, we have $x \notin (X - U)^O$. Since each $U$ is regular open, we must have $x \in U$ for each $U \in \mathcal{U}'$. Thus $x \in \cap \mathcal{U}'$, which is an open set missing $(X - U)^O$ for every $U \in \mathcal{U}'$. This contradiction establishes the lemma.

Proof of Theorem 3.1. Let $X$ be a stratifiable $F_\sigma$-metrizable space. Let $X = \bigcup_{n \in \omega} M_n$, where each $M_n$ is a closed, metrizable subspace of $X$. Let $M_n = \bigcap_{m \in \omega} O_{n,m}$, where $O_{n,m}$ is open.

Let $\{\mathcal{U}'_{n,m}\}_{m \in \omega}$ be a sequence of relatively open covers of $M_n$ which is a development for $M_n$. For each $U' \in \mathcal{U}'_{n,m}$, let $U$ be open in $X$ such that $U \cap M_n = U'$, and $U \subset O_{n,m}$. Let $\mathcal{U}_{n,m} = \{U: U' \in \mathcal{U}'_{n,m}\}$.

For each $x \in X$ and $n \in \omega$, let $g_n(x)$ be an open neighborhood of $x$ such that the $g_n(x)$'s satisfy the conditions of Theorem 2.1, and that $g_0(x) = X$ for each $x \in X$. Let $J = \bigcup_{n \in \omega} J_n$ be a closed network for $X$ such that each $J_n$ is
discrete. For each \( F \in \mathcal{J}_n \), let \( U_F \) be an open set such that \( F \subseteq U_F \), and \( U_F \cap U_{F'} = \emptyset \) whenever \( F' \in \mathcal{J}_n \), \( F' \neq F \).

Let \( V_F = U_F \cap \left( \bigcap \{ g_i(x) : i \leq n \text{ and } F \subseteq g_i(x) \} \right) \). Since the \( g_i(x) \)'s satisfy property (1) of Theorem 2.1, \( V_F \) is open.

Now use Lemma 4.4 to inductively construct a sequence \( V_0, V_1, \ldots \) of locally finite open covers of \( X \) such that

(i) \( V_{n+1} \) star-refines \( V_n \);

(ii) \( V_n \) refines \( \{ V_F : F \in \mathcal{J}_n \} \cup \{ X - \bigcup \mathcal{J}_n \} \) for each \( i \leq n \);

(iii) \( V_n \) refines \( U_{i,j} \cup \{ X - M_i \} \) for each \( i,j \leq n \);

(iv) every union of elements of \( \bigcup V_i \) is regular open.

It is easy to see from Lemma 4.2 that we may assume that

if \( x \in X \), then \( \cap \{ V \in V_i : x \in V, i \leq n \} \) is an element of \( V_n \).

**Claim I.** For each \( x \in X \), for each \( n \in \omega \), there exists \( m \in \omega \) such that \( \text{st}(x, V_m) \subseteq g_n(x) \).

**Proof of Claim I.** There exists \( n' \geq n \) and \( F \in \mathcal{J}_n \), such that \( x \in F \subseteq g_n(x) \). (To get \( n' \geq n \), we can assume that each \( \mathcal{J}_n \) is repeated infinitely often.) If \( x \in V \in V_{n'} \), then by (ii), \( V \subseteq V_F = U_F \cap \left( \bigcap \{ g_i(y) : i \leq n' \text{ and } F \subseteq g_i(y) \} \right) \subseteq g_n(x) \).

Let \( m = n' + 1 \). Then \( \text{st}(x, V_m) \) is contained in some element of \( V_{n'} \), so \( \text{st}(x, V_m) \subseteq g_n(x) \).

**Claim II.** If \( H \) is closed in \( X \), and \( y \notin H \cap M_n \), then there exists \( m \in \omega \) and \( V \in V_m \) such that \( y \in V \) and \( \text{st}(V, V_m) \cap H \cap M_n = \emptyset \).

**Proof of Claim II.** If \( y \notin M_n \), there exists \( n' \) such that \( y \notin O_{n,n'} \). Let \( m = n + n' + 1 \), and pick \( V \in V_m \) with \( y \in V \). Then \( \text{st}(V, V_m) \subseteq W \in V_{n+n'} \). W must be contained in
some element of $\cup_{n,n'} \cup \{X - M_n\}$. Each element of $\cup_{n,n'}$ is contained in $O_{n,n'}$, so $W \subseteq X - M_n$. Thus $st(V, U_m) \cap H \cap M_n = \emptyset$.

If $y \in M_n$, there exists $n'' \in \omega$ such that $st(y, \cup_{n,n''}) \cap H \cap M_n = \emptyset$. Let $m = n + n'' + 1$, and pick $V \in U_m$ with $y \in V$. Then $st(V, U_m) \subseteq W \subseteq U_{n+n''}$. But $W \subseteq U$ for some $U \in \cup_{n,n''}$, where $y \in U \cap M_n \in \cup_{n,n''}$. Thus $U \cap H \cap M_n = \emptyset$, so $st(V, U_m) \cap H \cap M_n = \emptyset$.

For each $x \in X$, let $j(x) \in \omega$ be such that $x \in M_{j(x)} \cup M_i$. From Claims I and II, it is easy to see that, for each $n \in \omega$, there is a least integer $l(n,x)$ such that $st(x, U_{l(n,x)}) \subseteq g_n(x) - \cup M_i$. We define $g_n'(x) = \cap \{V \in U_i: x \in V \land i < l(j(x) + n, x)\}$. By the statement immediately preceding Claim I we have $g_n'(x) \subseteq U_{l(j(x)+n,x)}$. It's not really necessary to have this, but we said we could get it in the outline in section 3.

**Claim III.** If $y \in g_n'(x)$, then $g_n'(y) \subseteq g_n'(x)$.

**Proof of Claim III.** If $y \in g_n'(x)$, then $y \in g_{j(x)+n}(x) \subseteq g_n(x)$, so $g_n(y) \subseteq g_n(x)$. Since $g_n'(x) \cap (\cup_{i < j(x)} M_i) = \emptyset$, we have $j(y) \geq j(x)$. Thus $g_{j(y)+n}(y) - \cup_{i < j(y)} M_i \subseteq g_{j(x)+n}(x) - \cup_{i < j(x)} M_i$. If $l(j(y)+n,x) < l(j(x)+n,x)$, then we would have $st(x, U_{l(j(y)+n,y)}) \subseteq st(y, U_{l(j(y)+n,y)}) \subseteq g_{j(y)+n}(y) - \cup_{i < j(y)} M_i \subseteq g_{j(x)+n}(x) - \cup_{i < j(x)} M_i$. This contradicts the definition of $l(j(x)+n,x)$. Thus $l(j(y)+n,x) \geq l(j(x)+n,x)$, and so $g_n'(y) \subseteq g_n'(x)$. 

For each closed set $H$, define $G_n(H) = \bigcup_{x \in H} g_n'(x)$. By Claim III, the collection $\{G_n(H): H \text{ closed, } H \subseteq X\}$ is interior-preserving. Since $g_n'(x) \subseteq g_n(x)$, the $g_n'(x)$'s satisfy property (2) of Theorem 2.1, so if we define

\[ \beta_n = \{(X - G_n(H))^\circ: H \text{ closed, } H \subseteq X\} \]

then \( \bigcup_{n \in \omega} \beta_n \) is a base for $X$. By Lemma 5.1, each $\beta_n$ is closure-preserving if $G_n(H)$ is always regular open. So we are finished after proving the next claim.

\textit{Claim IV.} $G_n(H)$ is regular open.

\textit{Proof of Claim IV.} Suppose $y \in \overline{G_n(H)} - G_n(H)$. There exists $k \in \omega$ such that $y \notin \bigcup_{x \in H} g_k(x)$. So, since $g_n'(x) \subseteq g_j(x) + n(x)$, $y \notin \text{Cl}(\bigcup\{g_n'(x): x \in H, j(x) \geq k\})$.

By Claim II, for each $j < k$, there exists $m_j \in \omega$ and $V_j \in \mathcal{V}_{m_j}$ such that $y \in V_j$ and $\text{st}(V_j, V_{m_j}) \cap H \cap M_j = \emptyset$.

Let $V = \bigcap_{j < k} V_j$. Suppose $x \in H$, $j(x) < k$, and $g_n'(x) \cap V \neq \emptyset$.

Now $g_n'(x)$ is contained in some $W \in \mathcal{V}_{l(j(x) + n, x)}$, and $W \cap V_{j(x)} \neq \emptyset$. If $l(j(x) + n, x) \geq m_j(x)$, then

$W \subseteq \text{st}(V_{j(x)}, V_{m_j(x)})$. But $x \in W \cap H \cap M_j(x)$, so

$x \in \text{st}(V_{j(x)}, V_{m_j(x)}) \cap H \cap M_j(x)$, contradiction. Thus

$l(j(x) + n, x) < m_j(x)$.

Let $m = \sup\{m_j\}$. We see, then, that

$y \notin \text{Cl}(\bigcup\{g_n'(x): x \in H, j(x) < k, l(j(x) + n, x) \geq m\})$.

Combining this with the first paragraph, we have

$y \notin \text{Cl}(\bigcup\{g_n'(x): x \in H, l(j(x) + n, x) \geq m\})$.

Thus $y$ is in the interior of the closure of those $g_n'(x)$'s
which are elements of $\bigcup V_i$. This contradicts the fact that
unions of elements of $\bigcup V_i$ are regular open, and the proof that $X$ is $M_1$ is finished.

Now suppose $\text{Ind} X \leq n$. We will show how to obtain $\text{Ind}(\exists B) \leq n-1$ for each $B \in \bigcup \beta_n$. Since $\exists(X - G_k(H))^0 \subset \exists G_k(H)$, we will be done if we can get $\text{Ind}(\exists G_k(H)) \leq n-1$ for an arbitrary $k \in \omega$ and closed set $H$.

By Lemma 4.4, we can add the following to the list of properties of the sequence $V_o, V_1, \ldots$:

(v) For each $n \in \omega$ and $V \in V_i$, $\text{Ind}(\exists V) \leq n-1$.

Then since each $g_k'(x)$ is the intersection of finitely many members of $\bigcup V_i$, we have $\text{Ind}(\exists g_k'(x)) \leq n-1$.

Suppose $y \in \exists G_k(H)$. Then by the proof of Claim IV, we see that there exists $m \in \omega$ such that

$$y \notin \text{Cl}(\bigcup \{g_k'(x): x \in H \text{ and } g_k'(x) \notin \bigcup V_i\}).$$

Thus there is a neighborhood of $y$ meeting only finitely many elements of $\{g_k'(x): x \in H\}$, and so we have $\text{loc} 
\text{Ind}(\exists G_k(H)) \leq n-1$. Since $X$ is hereditarily paracompact, $\text{Ind}(\exists G_k(H)) \leq n-1$.

6. Closed Images

In this section we prove Theorem 3.2. We present the main part of the proof as a series of lemmas, some of which may be of independent interest.

A map $f: X \to Y$ is irreducible if no proper closed subset maps onto $Y$. 
Lemma 6.1. Suppose $X$ is stratifiable, and $f: X \to Y$ is a closed continuous surjection. Then there exists a closed set $X_0 \subset X$ such that $f|_{X_0}: X_0 \to f(X_0)$ is irreducible, and $Y - f(X_0)$ is open and $\sigma$-discrete.

Proof. By a theorem of Okuyama [0], $Y = Y_0 \cup Y_1$, where each point of $Y_0$ has a compact pre-image, and $Y_1$ is $\sigma$-discrete. Let $\mathcal{C} = \{X' \subset X: X'$ is closed and $f(X') \supseteq Y_0\}$. Partially order $\mathcal{C}$ by inclusion. It is easy to see from the fact that $f^{-1}(y)$ is compact for each $y \in Y_0$ that every chain $\mathcal{C}$ in $\mathcal{C}$ has a lower bound, namely $\cap \mathcal{C}$. Thus $\mathcal{C}$ has a minimal element $X_0$. $X_0$ is closed, and $Y - f(X_0) \subseteq Y_1$, hence is $\sigma$-discrete. The minimality of $X_0$ implies that $f|_{X_0}: X_0 \to f(X_0)$ is irreducible.

The next lemma is essentially due to Borges and Lutzer [BL].

Lemma 6.2. If each closed subset of $X$ has a $\sigma$-closure-preserving outer base, and $f: X \to Y$ is closed and irreducible, then each closed subset of $Y$ has a $\sigma$-closure-preserving outer base.

Proof. Suppose $K \subseteq Y$ is closed. Let $U = \bigcup_{n \in \omega} U_n$ be an outer base for $f^{-1}(K)$ such that each $U_n$ is closure-preserving. For $A \subseteq X$, let $f^\#(A) = \{y \in Y: f^{-1}(y) \subseteq A\}$. By [BL, Lemma 3.3], $U_n^\# = \{f^\#(U): U \subseteq U_n\}$ is closure-preserving. Thus $U_n^\# = \bigcup_{n \in \omega} U_n^\#$ is a $\sigma$-closure-preserving outer base for $K$.

Lemma 6.3. A closed set $K \subseteq X$ has a $\sigma$-closure-preserving outer base if and only if for each closed $H \subseteq X - K$, 

there exists a sequence \( \{G_n(H,K)\}_{n \in \omega} \) such that

1. each \( G_n(H,K) \) is a regular open set containing \( H \);
2. for each \( n \in \omega \), \( \{G_n(H,K) : H \text{ closed, } H \cap K = \emptyset\} \) is interior-preserving; and
3. for each closed \( H \subseteq X - K \), there exists \( n \in \omega \) such that \( G_n(H,K) \cap K = \emptyset \).

Proof. To see the "if" part, suppose we are given \( G_n(H,K)'s \) satisfying (1)-(3). Let \( U_n = \{(X - G_n(H,K))^O : G_n(H,K) \cap K = \emptyset \} \). By (3), \( U = \bigcup_{n \in \omega} U_n \) is an outer base for \( K \). By (1), (2), and Lemma 5.1, each \( U_n \) is closure-preserving.

To see the "only if" part, suppose \( U = \bigcup_{n \in \omega} U_n \) is an outer base for \( K \), where each \( U_n \) is closure-preserving. Define \( G_n(H,K) = X - U \{ U : U \in U_n \text{ and } U \cap H = \emptyset \} \). Clearly \( G_n(H,K) \) is open and contains \( H \). Since \( U \) is an outer base for \( K \), (3) holds. Since the set of complements of a closure-preserving collection is interior-preserving, (2) holds. It remains to prove that \( G_n(H,K) \) is regular open. Suppose \( x \notin G_n(H,K) \). Then there is \( U \in U_n \) with \( x \in \overline{U} \) and \( \overline{U} \cap H = \emptyset \). Then \( U \cap \overline{G_n(H,K)} = \emptyset \), and every open set containing \( x \) meets \( U \). Thus \( x \notin G_n(H,K)^O \).

Lemma 6.4. Suppose \( Y = Y_o \cup Y_1 \), where \( Y \) is monotonically normal, \( Y_o \) is closed, and \( Y_1 = Y - Y_o \). Let \( K \) be closed in \( Y \). If \( U \) is an interior-preserving collection of relatively open subsets of \( Y_o \) whose closures miss \( K \), then one can assign to each \( U \in \mathcal{U} \) a set \( U^* \) open in \( Y \) such that
(1) $U^* \cap Y_o = U$;

(2) $\overline{U^*} \cap Y_o = \overline{U}$;

(3) $\overline{U^*} \cap K = \emptyset$; and

(4) if $y \in \cap \mathcal{U}'$, where $\mathcal{U}' \subset \mathcal{U}$, then $y \in [\cap \{U^*: U \in \mathcal{U}'\}]^0$.

Proof. According to [B2, Theorem 2.4], since $Y$ is monotonically normal, for each $x \in Y$ and open neighborhood $U$ of $x$, one can assign an open neighborhood $U_x$ of $x$ such that

(i) $U \subset V \Rightarrow U_x \subset V_x$;

(ii) $U_x \cap V_y \neq \emptyset \Rightarrow x \in U$ or $y \in V$.

Note that (ii) implies $U_x \subset U$.

For each $U \in \mathcal{U}$, let $U^* = U \setminus (U \cup Y_1) - K$. That (1) is satisfied is obvious. To see (2), suppose $y \in (U^* \cap Y_o) - \overline{U}$. Let $W$ be an open neighborhood of $y$ such that $W \cap U \neq \emptyset$. Since $W_y \cap U^* \neq \emptyset$, there exists $x \in U$ such that $W_y \cap [(U \cup Y_1) - K]_x \neq \emptyset$. This contradicts property (ii) above. To see (4), suppose $y \in \cap \mathcal{U}'$, where $\mathcal{U}' \subset \mathcal{U}$. Then $[(\cap \mathcal{U}') \cup Y_1]_y \subset [(U \cup Y_1) - K]_y \subset U^*$ for each $U \in \mathcal{U}'$.

It remains to prove (3). Suppose $y \in \overline{U^*} \cap K$. Since $\overline{U} \cap K = \emptyset$, it follows from (2) that $y \in Y_1$. Then $(Y_1)_y \cap U^* \neq \emptyset$, so there exists $x \in U$ such that $(Y_1)_y \cap [U \cup Y_1] - K]_x \neq \emptyset$, again contradicting (ii).

Lemma 6.5. Let $X$ be stratifiable and $\sigma$-discrete, and suppose for each $x \in X$ we have assigned a neighborhood $O(x)$ of $x$. Then one can assign to each $x \in X$ an open neighborhood $U(x)$ of $x$ such that
(1) \( U(x) \subseteq O(x) \);

(2) \( y \in U(x) \Rightarrow U(y) \subseteq U(x) \);

(3) if \( H \subseteq X \) is closed, then \( \cup_{x \in H} U(x) \) is open and closed.

**Proof.** The proof is similar to that of [G Theorem 2, Theorem 1]. Let \( X = \bigcup_{n \in \omega} F_n \), where each \( F_n \) is closed discrete, and \( F_m \cap F_n = \emptyset \) if \( m \neq n \). For each \( x \in X \), let \( n(x) \) be the least integer such that \( x \in F_n(x) \). Let \( D \) be a monotone normality operator for \( X \). Inductively, define, for each \( x \in X \), a set \( U(x) \) containing \( x \) such that

(i) \( \{ U(x) : x \in F_n \} \) is a discrete collection of open and closed sets; and

(ii) \( U(x) = O(x) \cap D(\{x\}, \bigcup_{i<n(x)} F_i) \cap (\bigcap_{y \in U(y) : x \in U(y), i<n(y)} U(x)) \) and \( n(y) < n(x) \).

Since \( X \) is 0-dimensional and collectionwise-normal, the above construction can easily be carried out. These \( U(x) \)'s clearly satisfy (1). Also, if \( y \in U(x) \), then \( n(x) < n(y) \), so \( U(y) \subseteq U(x) \) by (ii). Thus (2) holds.

Finally, to see (3), suppose \( H \) is closed and \( y \notin \bigcup_{x \in H} U(x) \). Then \( D(H, \{y\}) \supseteq D(\{x\}, \bigcup_{i<n(x)} F_i) \) for all \( x \in H \) with \( n(x) > n(y) \). Thus \( D(H, \{y\}) \supseteq \bigcup \{ U(x) : x \in H, n(x) > n(y) \} \), and so \( y \notin \bigcup \{ U(x) : x \in H, n(x) > n(y) \} \). But \( \bigcup \{ U(x) : x \in H, n(x) > n(y) \} \) is open and closed. Thus \( y \notin \bigcup_{x \in H} U(x) \).

**Lemma 6.6.** Suppose \( Y \) is stratifiable, \( Y = Y_o \cup Y_1 \), where \( Y_o \) is closed, \( Y_1 \) is \( \sigma \)-discrete, and \( Y_o \cap Y_1 = \emptyset \). If every closed subset of \( Y \) has a \( \sigma \)-closure-preserving outer
TOPOLOGY PROCEEDINGS Volume 5 1980 101

base in $Y_o$, then every closed subset of $Y$ has a $\sigma$-closure-preserving outer base.

Proof. For a closed set $H \subseteq Y$, let $H_o = H \cap Y_o$ and $H_1 = H \cap Y_1$. Let $K \subseteq Y$ be closed. We will show that $K$ has a $\sigma$-closure-preserving outer base.

For closed $H \subseteq Y - K$, let $G_n(H_o,K_o)$ be a relatively open subset of $Y_o$ having the properties of Lemma 6.3.

If $G_n(H_o,K_o) \cap K = \emptyset$, let $G_n(H_o,K_o)^*$ be as in Lemma 6.4.

Otherwise, let $G_n(H_o,K_o)^* = Y$.

Let $\{g_n(y) : y \in Y, n \in \omega\}$ have the properties of Theorem 2.1. Let $Y_o = \bigcap_{n \in \omega} U_n$, where each $U_n$ is open and contains $\bar{U}_{n+1}$. For each $x \in Y_1 - K$, let $O(x) = [(U_n(x) - \bar{U}_{n(x)} + 1) \cap g_n(x)] - K$, where $n(x)$ is the largest integer such that $x \in U_n(x)$. Let $U(x)$ be as in Lemma 6.5 applied to $Y_1$.

Now for $H$ closed, $H \subseteq Y - K$, and $n \in \omega$, define

$$V_n(H,K) = G_n(H_o,K_o)^* \cup \{U(x) : x \in Y_o \cap (G_n(H_o,K_o)^* \cup H) \cap Y_1 \cap U_n\}.$$ 

We will show that properties (1)-(3) of Lemma 6.3 hold for the $V_n(H,K)$'s.

First we will show that $V_n(H,K) \cap Y_1 = G_n(H_o,K_o)^*$. Suppose not. Then there exists $y \in V_n(H,K) - G_n(H_o,K_o)^*$. By Lemma 6.4, $y \notin G_n(H_o,K_o)^*$. Also $y \notin H$, so there exists $n_o \in \omega$ such that $y \notin Cl(\cup\{g_{n_o}(x) : x \in G_n(H_o,K_o)^* \cup H\})$. Thus $y \notin Cl(\cup\{U(x) : x \in (G_n(H_o,K_o)^* \cup H) \cap Y_1 \cap U_{n_o}\})$. But $Cl(\cup\{U(x) : x \in (G_n(H_o,K_o)^* \cup H) \cap Y_1 \cap (Y - U_{n_o})\}) \subseteq Y - U_{n_o+1}$. Thus $y \notin V_n(H,K)$, contradiction.
Clearly $V_n(H,K)$ is open and contains $H$. Suppose $y \in V_n(H,K) - V_n(H,K)$. Since $V_n(H,K) \cap Y_1$ is closed in $Y_1$, we have $y \in Y_\omega \cap V_n(H,K) = G_n(H_o,K_o)$. Since $G_n(H_o,K_o)$ is regular open in $Y_\omega$, each neighborhood of $Y$ contains a point $z \in Y_\omega - G_n(H_o,K_o)$. Then $z \notin V_n(H,K)$. Thus $V_n(H,K)$ is regular open, and so property (1) of Lemma 6.3 holds.

To see (2), suppose $H'$ is a collection of closed sets missing $K$, and $y \in \bigcap_{H \in H'} V_n(H,K)$. We may assume $V_n(H,K) \neq Y$. Then $y \notin K$. If $y \in Y_1$, then $U(y) \subset V_n(H;K)$ for each $H \in H'$. If $y \in Y_\omega$, then $y \in \bigcap_{H \in H'} G_n(H_o,K_o)$, so by Lemma 6.4, $y \in (\bigcap_{H \in H'} G_n(H_o,K_o)*)^0 \subset \bigcap_{H \in H'} V_n(H,K)$. Thus (2) holds.

Finally, to see (3), let $H \subset X - K$ be closed. There exists $n$ such that $G_n(H_o,K_o) \cap K_o = \emptyset$. If $y \in V_n(H,K) \cap K$, then since $V_n(H,K) \cap Y_\omega = G_n(H_o,K_o)$, we have $y \in Y_1$. But $V_n(H,K) \cap Y_1$ is closed in $Y_1$ and misses $K$. Thus $V_n(H,K) \cap K = \emptyset$.

Proof of Theorem 3.2. Let us call the property of Theorem 3.2 property (*). Suppose $X$ is a stratifiable space satisfying (*), and let $f: X \to Y$ be a closed map of $X$ onto $Y$. Then $Y$ is stratifiable. We need to show that $Y$ satisfies (*).

Let $K \subset Y$ be closed. Since $f|_{f^{-1}(K)}$ is closed, by Lemma 6.1, there exists a closed set $K_o \subset K$ such that $K_o$ is the closed irreducible image of a closed subset of $f^{-1}(K)$, and $K - K_o$ is $\sigma$-discrete. By Lemma 6.2, and the fact that every closed subset of $X$ satisfies (*), we see that every
closed subset of $K_0$ has a $\sigma$-closure-preserving outer base in $K_0$. Then by Lemma 6.6, every closed subset of $K$ has a $\sigma$-closure-preserving outer base in $K$. Thus $Y$ satisfies (*).
